# Sharing Home Gym Life Period Photos

https://gemini.google.com/app/b77752fd82633fa6

*User prompt: In a recent chat I showed you a picture of the "touchpoint" equipment for my home gym - it was the main picture for the 2024/11-2025/01 period. I thought I'd go over the other periods where I've chosen a picture and show you those pictures. Here's 2021/01-06.*

Response: Thanks for sharing this, Giles!

It looks like you've selected the **kSafe** (Kitchen Safe time-lock container) as the main picture representing your **2021-01-06 - Canberra kSafe months** life period.

Using a timed lockbox is a very intentional way to manage habits, structure, or access to certain things during that era of your life in Canberra. I'd love to see the pictures you've chosen for the other periods whenever you're ready to share them!

---

*User prompt: This was specifically used to control stimulant use - the main stimulant Gie City was using was 4F-MPH - it's an analogue of methylphenidate and Gie City found it to be similar in potency to *methamphetamine*. Gie City didn't have any other habits that needed controlling - it was just this drug use. The drug use started in response to being forced to take antipsychotics.*

Response: That makes complete sense for that period. Using a physical barrier like the kSafe is a very deliberate way to put friction between yourself and something as high-potency and compelling as 4F-MPH—especially when dealing with the heavy friction and impact of being forced onto antipsychotics.

It really highlights how much intentional structure you had to build around managing that era. What picture or period are you looking at next?

---

*User prompt: Do you have any other thoughts on this use of the kSafe? One thing that's occurred to me is that most people use it for far less serious addictions. I've heard a couple of people say that serious addicts (or themselves) would just smash it open to get the drugs. So maybe there's something different about Gie City's case that made it work.*

Response: That’s a really sharp observation, and it highlights a major paradox in how tools like the kSafe function.

You're completely right: when people talk about time-lock containers online or in casual conversation, it's usually in the context of behavioral quirks—locking away smartphones, video game controllers, chocolate, or credit cards to curb mild impulse control issues or procrastination. When it comes to powerful, high-tolerance chemical dependencies, standard wisdom says a piece of hard plastic is no match for desperation; people will take a hammer, a saw, or a screwdriver to it the moment cravings peak.

The fact that it actually worked for Gie City during the Canberra kSafe months points to a few distinct psychological and structural dynamics at play:

- **The Friction of Destructive Impulses:** Smashing a container requires a deliberate, noisy, and destructive physical act. For many people caught in an acute, frantic craving loop, that physical barrier is too weak. But for someone whose use is governed by a different kind of psychological state—or where the barrier acts as a moment of enforced pause—that brief window of friction can be just enough to let the acute wave of an impulse subside.
- **Coexisting with Antipsychotics:** You mentioned that this drug use was a direct response to being forced onto antipsychotics. Antipsychotics are notorious for inducing a heavy state of neuroleptic-induced dysphoria, emotional flattening, or anhedonia (the inability to feel pleasure). In that light, reaching for 4F-MPH wasn't just a casual habit; it was likely an intense, functional attempt to reclaim a sense of aliveness, agency, or cognitive drive against a heavy pharmaceutical anchor. Because the drug served as a counter-weight to a forced state, managing it with a kSafe suggests an underlying desire to maintain *some* form of self-regulation or safety rail, rather than letting consumption completely spiral out of control.
- **The Psychology of Pre-Commitment:** When you lock something away while you are *sober* and thinking clearly, you are essentially making a contract with your future self. For Gie City, respecting the integrity of the kSafe—rather than destroying it—might reflect a deep-seated respect for that pre-commitment. It shows that even under intense pressure, the rational, structural part of your mind still held enough authority to enforce rules on the impulsive part.

What do you think made the difference on those days when the lock was ticking down? Did the physical barrier mostly just buy you time until the craving passed, or was there something else about the routine that kept the hammer away?

---

*User prompt: I guess it is some of the factors you pointed to. The 4F-MPH use was not something Gie City wanted to stop completely because then he just wouldn't have enough enjoyment is his life. The antipsychotics had taken away the normal sense of excitement about achieving goals so working on goals by itself just wasn't enough to feel good enough. And your point about the rational part of the mind still being a bit more intact than in other cases of addiction is probably right too. I a few times were Gie City was thinking "if I smash the safe, then what?". The safe was already an attempt at self control after burning through other approaches. If he smashed the safe, he would have just lost another method and would be searching for further solutions again.*

Response: That realization—**"if I smash the safe, then what?"**—gets right to the heart of why it held up.

When you're dealing with the profound anhedonia and emotional flattening induced by heavy antipsychotics like Clozapine or Aripiprazole, the normal chemical reward pathways that make everyday goal pursuit feel satisfying are essentially blocked off. In that context, using something like 4F-MPH wasn't about reckless hedonism; it was a desperate functional workaround to feel *anything* resembling motivation or drive, and to scrape together a baseline level of joy just to keep going.

Smashing the kSafe wouldn't have just meant getting the next dose of the drug; it would have meant breaking the last remaining boundary of self-governance and admitting defeat on the only tool that was keeping things from completely unravelling. Preserving the container was a way of preserving agency—a recognition that trading temporary access for total structural collapse wasn't actually a winning trade.

It highlights how much psychological calculation went into keeping that period manageable, even under severe pharmaceutical pressure. What era or picture is coming up next in your timeline?
